

Real-Time Retail CPI For Bolivia*

Thomas Riveros[†]

August 23, 2026

Abstract

Official inflation metrics, while robust, suffer from publication lags due to traditional in-person surveying methods. To address this critical reporting gap, I construct a real-time, synthetic Retail Price Index for Bolivia utilizing daily web-scraped supermarket data from a major national chain. Employing an AI-driven classification pipeline, I map over 28,000 unique products across three major cities to a “core-5” basket aligned with official Instituto Nacional de Estadística (INE) categories. I then use a chained Jevons index to calculate and aggregate daily price relatives. The resulting synthetic index demonstrates a strong correlation with official INE data, achieving coefficients up to 0.99 for index levels and 0.80 for month-over-month inflation. Furthermore, regression analysis reveals that the daily synthetic index serves as a statistically significant leading indicator, with 15-day and 20-day lags successfully predicting overall official inflation. Ultimately, this real-time tracker equips policymakers with an essential, high-frequency tool to monitor price dynamics in real time and preempt future inflationary pressures.

1 Introduction

In the summer of 2025, Bolivia suffered its worst inflation episode in over 40 years. Prices rose by 20% year-over-year in 2025, and real GDP fell by 1.2% on an annual basis [1] [2]. The fall in output was primarily due to large real declines in commerce and mineral extraction [3]. The stagflationary environment contributed to a projected rise in the poverty rate (defined here as the share of the population living below \$4.20 in 2021 PPP terms) from 4.9% in 2024 to 6.4% in 2025 [4]. Bolivians’ suffering translated into a resounding defeat of the incumbent party, Movimiento al Socialismo (MAS), in the 2025 presidential election.

While the government blamed rampant speculation and international inflationary pressures, more plausible explanations include a sharp increase in the money supply resulting from debt monetization, an artificial gas shortage created by subsidies, unanchored inflation expectations, and dollar

*I leveraged artificial intelligence to synthesize existing literature, code the data ingestion and calculation pipeline along with the webpage, and format and edit writing.

[†]Many thanks to my advisor, Julieta Caunedo, for her guidance and support.

shortages caused by capital, currency, and export controls. If the newly elected Paz administration wishes to permanently vanquish the specter of a rising price level, it must be equipped with the highest-frequency data possible.

Although the INE (Instituto Nacional de Estadística) publishes a robust monthly CPI, its methods rely on traditional in-person surveying, creating substantial lags between price observation and publication [1]. Researchers such as Alberto Cavallo and Roberto Rigobon pioneered real-time CPI measurement using web-scraped data from major Latin American supermarkets [5]. In their 2013 paper, “Online and official price indexes: Measuring Argentina’s inflation,” Cavallo and Rigobon laid out a methodology for constructing a real-time CPI. I apply that methodology to a large Bolivian supermarket chain to create a real-time retail CPI for the Bolivian economy.

2 Methodology

2.1 The Supermarket

The supermarket’s prices are collected daily by a scraper coded by Mauricio Foronda and updated live on GitHub [6]. The chain is one of the largest in Bolivia and has more than 30 locations across La Paz, Santa Cruz, and Cochabamba, allowing me to construct city-specific CPIs. The company sells a wide range of products with more than 28,000 unique IDs, and that product universe changes over time as items are added and removed. Product subcategories are summarized in Table 9. Given the retailer’s size and product offerings, the resulting index provides a reasonable estimate of formal supermarket prices.

2.2 Product Categorization

Although the supermarket’s own subcategories provide substantial granularity, I wanted to ensure that each of the more than 28,000 products was mapped into one of the 12 official INE categories using the Classification of Individual Consumption According to Purpose (CCIF). To do so, I used an AI-coded application trained on the official methodology and had it categorize each product individually. The categorizer included additional categories because the CCIF places Food (and Beverages) Consumed Away from Home within Restaurants and Hotels, whereas the INE methodology only includes Food Consumed Away from Home in the CPI. I exclude that category from the final analysis because of its small sample size.

To deal with newly added products, I used an AI-coded program that draws from a persistent historical mapping dictionary (`mappings/Final_Complete_Categories.csv`) to identify known products. When a new product is added, the script recognizes it and queries the Gemini 2.5 Flash model. The model is provided with the official INE 2016 Methodology PDF and the CCIF categorization guidelines as strict context. It is forced to output a JSON payload classifying the new item into one of the designated core categories (or “Unmapped” if inapplicable). The AI’s decisions are appended back to the master CSV, ensuring the API is only queried for novel products.

2.3 The Core Basket

Table 1: Core-5 Expenditure Categories and Weights

Category	Raw Weight	Normalized Weight (%)
Food and Non-Alcoholic Beverages	27.06	55.08
Clothing and Footwear	7.56	15.39
Miscellaneous Goods and Services	7.55	15.37
Furniture, Household Goods and Services	6.08	12.38
Alcoholic Beverages and Tobacco	0.88	1.79

Because the supermarket either had low observation counts in some divisions, such as communications, or clearly did not represent the same basket of goods covered by the official CPI, such as transportation or housing, I defined a “core-5” basket designed to track the INE measure more accurately. This core basket combines high product counts with substantial within-category coverage. For example, although Recreation and Culture contains more than 1,000 unique products, its within-category coverage is still limited because the official INE basket also includes items such as sporting event tickets, movies, and tourist packages.

2.4 Other Filtering

Any product tagged seasonal (temporada) is removed from the sample due to the artificial downward bias it introduces into the index. For example, the Temporada Navideña (Christmas Season) has no listings throughout the year except directly before Christmas, when the prices spike and after which they fall dramatically and are removed. Because my methodology utilizes daily price relatives, when these prices drop and are later removed without a price increase, they bias the index calculation downwards.

2.5 Elementary Jevons Index

The core calculation relies on a chained Jevons index, the standard geometric formula used by Cavallo (2013) for elementary aggregate inflation when product substitution is likely.

Step A: Day-over-Day Relatives

For every active product, the daily relative price change is calculated against its immediately previous observed price:

$$\text{RelativeDOD}_{i,t} = \frac{\text{Price}_{i,t}}{\text{Price}_{i,t-1}}$$

Missing prices are omitted from the daily relative calculation, ensuring that the index only moves when a price change is actively observed.

Step B: Attrition and Imputation Limit (40-Day Rule)

The pipeline enforces a strict 40-day inclusion limit. If a product is unobserved for more than 40 consecutive days, it is treated as permanently dropped from the matched-model sample. If the exact same product reappears on day 41 or later, its day-of-return relative is nullified. The product then establishes a new base price for the following day, preventing artificial index spikes generated by severely outdated baseline prices while keeping the overall CPI structure intact.

Step C: Elementary Jevons Aggregate

Within each city (c) and category (k), the elementary index for day t is the geometric mean of all constituent product relatives:

$$\text{JevonsMean}_{c,k,t} = \exp \left(\frac{1}{n} \sum_{i=1}^n \ln (\text{RelativeDOD}_{i,t}) \right)$$

Step D: Time-Series Chaining

The daily geometric means are chained sequentially using a cumulative product to construct a continuous time series anchored at 100:

$$\text{ChainedIndex}_{c,k,t} = \text{ChainedIndex}_{c,k,t-1} \times \text{JevonsMean}_{c,k,t}$$

2.6 Aggregation

Once the elementary category indices are calculated, they are aggregated upward to form macroeconomic indicators.

City-Level Aggregation

For a given city, the overall CPI is the weighted arithmetic average of its five core category indices using the normalized weights established earlier in the paper:

$$\text{CityCPI}_{c,t} = \sum_k (\text{ChainedIndex}_{c,k,t} \times \text{NormalizedWeight}_k)$$

National Aggregation

The national CPI is computed as the weighted arithmetic average of the three metropolitan indices using official demographic or economic weights:

- Santa Cruz: 41.47%

- La Paz: 39.10%
- Cochabamba: 19.43%

$$\text{NationalCPI}_t = \sum_c (\text{CityCPI}_{c,t} \times \text{RegionalWeight}_c)$$

Daily Forward-Filling & N-Counts

To keep the tracker continuous, I forward-fill any missing dates with the previous date’s level. The need to employ this method is rare, with only 10 days being forward-filled throughout the entire sample period.

The pipeline also continuously tracks the number of relative price counts by each category to allow users to monitor data degradation and days with low observations. The measure adds price-relative observations across cities, treating each product-city combination as a unique observation, meaning that a single product sold across the three cities will be counted three times, as it provides different pricing information within each city.

Automation Infrastructure

The entire pipeline runs via a GitHub Actions Cron Job at 12:00 UTC (8:00 AM local time) daily. The runner uses a Python 3.10 environment, triggers the AI mapping for novel IDs, runs the calculations, and commits the updated historical .csv and .json artifacts back to the repository.

3 Results

Table 2 reports summary statistics for the full distribution of day-over-day price relatives. Category-level summary statistics are reported in Appendix Table 6.

Table 2: Overall Price Relative Summary Statistics

N	Min	P25	Median	Mean	Geom Mean	P75	Max	SD
21,199,211	0.0101	1	1	1.0007	1.0005	1	108.4722	0.0344

Here we see that the median and mean price relatives remain centered around one, with most observations concentrated at that value. Some products nonetheless display implausibly large one-day jumps. For example, Salsa BBQ Sauce Hot Promos 510 gr (ID: 832253) moves from \$5 at the official exchange rate to \$557 in a single day before later being corrected back to \$5.6. While this event is clearly a reporting glitch, imposing an arbitrary cap or floor on price relatives could introduce bias into the estimates. For instance, if a product priced at \$0.01 were adjusted to \$1 during a high-inflation episode, the implied relative of 100 would likely be removed by any reasonable outlier rule despite being valid.

The geometric average mitigates the influence of these extreme observations by allowing for substitution within categories. Appendix Figure 6 illustrates the geometric mean as a function of a single outlier price relative while all other product prices remain fixed. At a sample size of 6000, roughly the city-average number of food and beverage price relatives, the marginal effect of one outlier is small and declines as the outlier grows. For these reasons, I do not apply a range constraint to “reasonable” price relatives, because doing so could introduce bias.

Figure 1: Retail CPI compared with the reweighted official CPI and the overall CPI.

The level and month-over-month inflation estimates for the official data and the synthetic tracker move together with little divergence. Both the “core-5” official CPI and the real-time tracker appear to act as leading indicators for overall CPI. From May to August 2025, the real-time CPI rises before the overall CPI does, implying that information could have been used to inform policy well before overall inflation registered the price acceleration.

CPI levels between the synthetic tracker and official data are highly correlated, with the synthetic national and official national (“core-5”) having a coefficient of 0.99. Official and synthetic Santa Cruz have a coefficient of 0.98, while Cochabamba and La Paz have 0.98 and 0.99, respectively. The synthetic correlation with the official overall CPI (full 12 categories) remains high with a coefficient of 0.97, despite the compositional differences between the two. Inflation rates between the synthetic and official data are also correlated. Synthetic national inflation and official national inflation (“core-5”) have a coefficient of 0.8. For the city-level data, Santa Cruz synthetic inflation and official (“core-5”) inflation have a coefficient of 0.72, while Cochabamba and La Paz have 0.71 and 0.7, respectively. Finally, national synthetic inflation and overall official inflation (full 12 categories) have a coefficient of 0.71.

Overall, the synthetic CPIs tend to stay within 2–3 units of their official counterparts, while synthetic inflation measures remain within 1–2 percentage points of their official equivalents on average. The one exception is that there is a larger average absolute gap (6.04 units) between the national overall (full 12 categories) CPI and the synthetic CPI.

Figure 2: Correlation matrix of national and city-level CPI and inflation for the overall CPI, the equivalent “core-5” CPI, and synthetic inflation estimates

Table 3: Mean Absolute Difference (MAD) between Synthetic and Official CPI

Region	Metric	Mean Absolute Difference
Cochabamba	Index	2.302
La Paz	Index	2.793
National (“core-5”)	Index	2.146
National Overall	Index	6.039
Santa Cruz	Index	2.250
Cochabamba	Inflation	1.470
La Paz	Inflation	1.380
National (“core-5”)	Inflation	1.257
National Overall	Inflation	1.374
Santa Cruz	Inflation	1.534

Figure 3: Relationship between 15-day lagged synthetic inflation and official “core-5” inflation. Includes OLS and Iteratively Reweighted Least Squares lines.

Figure 4: Relationship between 15-day lagged synthetic inflation and official overall inflation, full 12 categories. Includes OLS and Iteratively Reweighted Least Squares lines.

Figure 5: Relationship between 20-day lagged synthetic inflation and official overall inflation, full 12 categories. Includes OLS and Iteratively Reweighted Least Squares lines.

All three scatter plots suggest a positive linear relationship between lagged synthetic inflation and realized official inflation. Interestingly, synthetic inflation is more strongly correlated with the overall inflation (full 12 categories) than with “core-5” inflation.

Table 4: Robust Regression Estimates: Predicting Official Overall Inflation

Predictor Variables	Dependent Variable: Official National Overall Inflation	
	Model 1 (15-Day Lag)	Model 2 (20-Day Lag)
Intercept	0.716*** (0.211)	0.726*** (0.204)
Synthetic_Lag_15	0.467*** (0.075)	
Synthetic_Lag_20		0.450*** (0.071)
Model Diagnostics		
Observations	18	18
Residual Std. Error	0.722	0.808

*Note: Robust standard errors in parentheses. * $p < 0.1$; ** $p < 0.05$; *** $p < 0.01$*

Table 4 depicts two regression models with official overall inflation as the dependent variable and lagged synthetic inflation (15 and 20-day lags) as the independent variables. A one percentage point increase in synthetic inflation is associated with a 0.47 percentage point increase at the 15-day horizon and a 0.45 percentage point increase at the 20-day horizon.

4 Discussion

The synthetic index closely mirrors both the equivalent “core-5” CPI measure and overall CPI. CPI correlation coefficients range from 0.97 to 0.99, and MADs range from 2.3 to 2.8 index points (except for when compared to the overall CPI, which is 6). Likewise, although the relationship is not as strong, month-over-month synthetic inflation matches official inflation quite well. Correlation coefficients range from 0.70 to 0.80, and MADs are around 1.20 to 1.53 percentage points.

The very limited data also appears to suggest some degree of predictive power of the MoM (measured daily) synthetic inflation tracker on subsequent inflation. Surprisingly, the relationship is strongest between lagged synthetic inflation and official overall inflation (full 12 categories). A one percentage point increase in 15-day lagged synthetic inflation is associated with a 0.47 percentage point increase in overall inflation; this result is significant at the 0.01 level and also holds up at a 20-day lag. The coefficients of 0.47 and 0.45 (15-day and 20-day lag, respectively) are structurally consistent given that my index covers 49% of the overall CPI. It should be noted that with so few observations, the predictive power of the synthetic CPI may significantly change as time progresses.

Given the severity of the recent crisis, inflation will likely remain on the minds of many Bolivians even as it continues to cool. For the Bolivian government to deliver on its promise of low inflation, it must rein in fiscal deficits (and debt monetization), continue with the elimination of the fuel subsidy, and pursue growth-promoting policies such as financial and trade liberalization. A real-

time measure of the variable of interest not only allows policymakers to see the instantaneous impacts of new legislation but also allows them to preempt inflationary or deflationary pressure with countercyclical fiscal and/or monetary policy.

5 Appendix Tables

Table 5: INE Weights by Division

Division	Weight
Food and Non-Alcoholic Beverages	27.06
Alcoholic Beverages and Tobacco	0.88
Clothing and Footwear	7.56
Housing and Basic Services	8.56
Furniture, Household Goods and Services	6.08
Health	3.55
Transport	9.07
Communications	5.43
Recreation and Culture	6.22
Education	4.07
Food Consumed Away from Home	13.95
Miscellaneous Goods and Services	7.55

Figure 6: Geometric mean response to a single outlier price relative. Here, x is the outlier, and $y = (x \cdot 1)^{1/6000}$ is the geometric mean of 6,000 price relatives (assuming all other relatives stay at 1).

Recreation and Culture	1,535
Restaurants and Hotels	4
Health	122
Transport	57
Housing and Basic Services	41

Table 8: Summary Statistics: Time Between Price Observations

Statistic	Value
<i>Panel A: Distribution of Observation Gaps (Days)</i>	
Minimum	1.000
1st Quartile	1.000
Median	1.000
Mean	1.135
3rd Quartile	1.000
Maximum	636.000
<i>Panel B: Tail Risk (Percentiles)</i>	
50th Percentile	1.000
75th Percentile	1.000
90th Percentile	1.000
95th Percentile	1.000
99th Percentile	2.000
<i>Panel C: Churn Frequency</i>	
Observations with Gap > 1 Day	1.21%

Notes: Table displays the empirical distribution of days between successfully scraped price observations for individual product SKUs across all surveyed cities.
