

Synthetic Daily CPI Tracker Methodology

This document outlines the end-to-end methodology used to construct the daily synthetic Consumer Price Index (CPI) tracker for Bolivia. The pipeline operates autonomously, pulling raw supermarket data (scraped by Mauricio Foronda), applying AI-driven categorizations, and calculating a mathematically robust, chained Jevons index that mirrors official INE (Instituto Nacional de Estadística) structures. The method was adapted from Alberto Cavallo’s 2013 paper: “Online and official price indexes: Measuring Argentina’s inflation.”

1 Data Ingestion & Preprocessing

The tracker relies on daily web-scraped price data from Bolivia’s largest supermarket chain (30+ locations) with stores in **La Paz, Santa Cruz, and Cochabamba**. The retailer has over 28,000 unique products in many different categories.

- **Frequency:** Daily data extraction.
- **Sanitization:** Raw identifiers (`id_producto`) are stripped of special characters, lowercased, and standardized using a `normalize_id` function to prevent duplication.
- **Temporada Filtering:** Any product explicitly tagged as seasonal (`temporada`) in its metadata or name is structurally excluded. This mitigates excessive noise and extreme price volatility that is not representative of core inflation trends.

2 Product Categorization & AI Mapping

To align supermarket SKUs with official macroeconomic data, each product is mapped to the standard **Classification of Individual Consumption According to Purpose (CCIF)**. An initial mapping of the 28,000 products was done by an AI-coded application trained on the Instituto Nacional de Estadística’s CCIF.

- **Master Mapping:** A persistent historical mapping dictionary (`mappings/Final_Complete_Cate`) is loaded into memory to categorize known products instantaneously.
- **AI-Driven Discovery:** When the ingestion pipeline encounters an unseen product ID, it extracts the product name and queries the **Gemini 2.5 Flash** model.
- **Context Injection:** The model is provided with the official *INE 2016 Methodology PDF* and the *CCIF categorization guidelines* as strict context. It is forced to output a JSON payload classifying the new item into one of the designated **core categories** (or “Unmapped” if inapplicable).

- **Persistent Storage:** The AI’s decisions are appended back to the master CSV, ensuring the API is only queried for *novel* products, drastically reducing operational costs.

3 Core Basket & Weights

The synthetic CPI **does not** cover all 12 INE categories because the supermarket does not sell products related to all categories, such as housing or transportation. Instead I define a “Core-5” basket, which gives 49.13% coverage of the official CPI.

Table 1: Core-5 Category Weights

Category	Raw Weight	Normalized Weight
Alimentos y Bebidas No Alcohólicas	27.06	55.08%
Prendas de Vestir y Calzados	7.56	15.39%
Bienes y Servicios Diversos	7.55	15.37%
Muebles, Bienes y Servicios Domésticos	6.08	12.38%
Bebidas Alcohólicas y Tabaco	0.88	1.79%

(Note: Raw weights are normalized out of their sum (49.13) so the resulting sub-basket sums to 100%).

4 Index Calculation

The core calculation relies on a **Chained Jevons Index**, the standard geometric formula used by Cavallo (2013) for elementary aggregate inflation where product substitution is likely.

Step A: Day-Over-Day (DOD) Relatives

For every active product, the daily relative price change is calculated against its immediate previous observed price:

$$RelativeDOD_{i,t} = \frac{Price_{i,t}}{Price_{i,t-1}}$$

(Missing prices are omitted from the daily relative calculation, ensuring the index only moves when a price change is actively observed).

Step B: Attrition and Imputation Limit (40-Day Rule):

The pipeline enforces a strict 40-day inclusion limit. If a product is unobserved for more than 40 consecutive days, it is considered permanently dropped from the matched-model sample. If the exact same product reappears on day 41 or later, its day-of-return relative is nullified. The product simply establishes a new base price for the following day, preventing artificial index spikes from severely obsolete baseline prices while keeping the overall CPI structurally intact.

Step C: Elementary Jevons Aggregate

Within each city (c) and category (k), the elementary index for day t is the geometric

mean of all constituent product relatives:

$$JevonsMean_{c,k,t} = \exp \left(\frac{1}{n} \sum_{i=1}^n \ln(RelativeDOD_{i,t}) \right)$$

Step D: Time-Series Chaining

The daily geometric means are chained sequentially using a cumulative product to construct a continuous time series anchored at 100:

$$ChainedIndex_{c,k,t} = ChainedIndex_{c,k,t-1} \times JevonsMean_{c,k,t}$$

5 Aggregation

Once the elementary category indices are calculated, they are aggregated upwards to form macroeconomic indicators.

City-Level Aggregation

For a given city, the overall CPI is the weighted arithmetic average of its 5 core category indices using the normalized weights established in Section 3:

$$CityCPI_{c,t} = \sum_k (ChainedIndex_{c,k,t} \times NormalizedWeight_k)$$

National Aggregation

The National CPI is computed as the weighted arithmetic average of the three metropolitan indices, based on official demographic/economic distributions:

- **Santa Cruz:** 41.47%
- **La Paz:** 39.10%
- **Cochabamba:** 19.43%

$$NationalCPI_t = \sum_c (CityCPI_{c,t} \times RegionalWeight_c)$$

6 Daily Forward-Filling & N-Counts

- **Imputation:** To guarantee a continuous daily time series (even on holidays where scrapers may fail), final index values are forward-filled (`ffill`).
- **N-Counts:** The pipeline simultaneously counts the number of valid observations per category per day. This metadata is saved to `supermarket_1_daily_n_counts.csv` to monitor sample size health and identify data degradation.

7 Automation Infrastructure

The entire pipeline runs via a **GitHub Actions Cron Job** at 12:00 UTC (8:00 AM local time) daily. The runner instantiates a Python 3.10 environment, triggers the AI mapping for novel SKUs, runs the vectorized calculations, and seamlessly commits the updated historical `.csv` and `.json` artifacts back to the repository.

8 Complete List of Hipermaxi Subcategories by Record Volume

Table 2: Complete List of Hipermaxi Subcategories by Record Volume

Subcategory	Record Count
Skin Care	1,800,677
Hair Care	1,336,777
Basics / Staples	884,422
Coffee & Substitutes	695,349
Wines & Champagne	649,930
Condiments & Legumes	636,724
Cookies & Crackers	607,444
Chocolates & Candies	593,662
Laundry Care	566,359
Snacks	559,747
Liquors & Spirits	551,504
Infant Nutrition	535,377
Home Accessories	493,899
Oral Care	456,611
Various Candies	445,672
American Products	433,773
Cold Cuts (External Brands)	404,715
Diet & Healthy	402,618
Dressings	398,756
Baking / Pastry	370,956
Bathroom Cleaners	360,144
Living Room & Closet Cleaners	348,292
Baby Care	305,419
Frozen Meats	305,036
Ice Cream, Cassatas & Popsicles	299,267
Family Care	290,566
Kitchen Cleaners	264,906
Canned Meals	264,748
Jams & Honeys	248,437
Cheeses	241,689
Canned Vegetables	239,229
